**CLAIMS** 

We claim:

1. In a local server that receives data from one or more remote clients over

a data transport protocol, a method of generating an initial sequence number for use by

a remote client when assigning sequence numbers to one or more data packets to be sent

to the local server, the initial sequence number generated in a manner that prevents the

local server from being attacked while maintaining reliable data transfer, the method

comprising the acts of:

generating a random input key using arbitrary information maintained secret by

the local server;

receiving a connection identifier key that includes connection information for at

least the remote client:

securely initializing a hash function with at least a portion of the random input

key and at least a portion of the connection identifier key for determining an

intermediate value of an initial sequence number;

creating a monotonically increasing counter for ensuring that a same connection

identifier does not have data collisions from competing sequence numbers within a

predetermined period of time, and for ensuring randomness of the initial sequence

number on a per connection basis for preventing attacks on the local server;

incrementing the counter a fixed value based on a passage of a predetermined

time period;

incrementing the counter a variable amount depending upon a rate of

connections with the local server, wherein if the rate of connections is beyond a

threshold value the variable increment is based on an elapsed time, otherwise the

variable increment is based on each connection established with the local server; and

combining the intermediate value, the fixed value and the variable amount for

generating the initial sequence number.

2. The method of claim 1, wherein if the rate of connections is below the

threshold value, the fixed value is further incremented based on each connection

established with the local server.

3. The method of claim 2, wherein based on the fixed value, if a remote

client's data transfer rate while connected to the local server is less than a specified byte

rate then the connection identifier used by the remote client the is allowed immediate

re-connection to the local server after the remote client disconnects.

4. The method of claim 1, wherein the connection identifier key further

includes connection information for one or more of the local server port, local server

routing address, remote port and remote routing address.

5. The method of claim 4, wherein the data transport protocol is

Transmission Control Protocol, and wherein the local and remote routing addresses are

Internet Protocol addresses.

6. The method of claim 1, wherein at least a second connection is made

between the local server and a second remote client, and wherein the method further

including the acts of:

receiving a second connection identifier key that includes connection

information for at least the second remote client;

securely initializing the hash function with at least a portion of the random input

key and at least a portion of the second connection identifier key for determining a

second intermediate value of a second initial sequence number;

based on at least a portion of the second connection identifier key, creating a

second monotonically increasing counter for ensuring that a same connection identifier

does not have data collisions from competing sequence numbers within a predetermined

period of time, and for ensuring randomness of the second initial sequence number on a

per connection basis for preventing attacks on the local server;

incrementing the second counter the fixed value based on the passage of the

predetermined time period;

incrementing the second counter a second variable amount depending upon a

rate of connections with the local server and for those connections associated with the

second counter, wherein if the rate of connections with the local server and for those

connections associated with the second counter is beyond a threshold value the variable

increment is based on an elapsed time, otherwise the variable increment is based on

each connection established with the local server and associated with the second

counter; and

combining the second intermediate value, the fixed value and the second

variable amount for generating the second initial sequence number.

Docket No. 13768.491

7. The method of claim wherein 1, wherein the arbitrary information

maintained as a secret by the local server is based on timing, state conditions for the

local server, or both, at boot up time of the local server, which include one or more of a

time of day, a day of month, a month, a year, a local server hard drive head position,

and whether input was detected by hardware of the local server.

8. The method of claim 1, wherein the combining of the intermediate value,

the fixed value and the variable amount is a mathematical operation or function.

9. The method of claim 1, wherein if the rate of connections is beyond the

threshold value the variable increments up to an amount of 0x000022FB every

millisecond, otherwise the variable increment is an amount between 16 K and 32 K.

10. The method of claim 1, wherein the monotonically increasing counter is

shared by at least two connections at the same time.

11. In a local server that receives data from one or more remote clients over

a data transport protocol, a method of generating an initial sequence number for use by

a remote client when assigning sequence numbers to one or more data packets to be sent

to the local server, the initial sequence number generated in a manner that prevents the

local server from being attacked while maintaining reliable data transfer, the method

comprising the steps for:

determining an intermediate value of an initial sequence number by hashing a

random input key and a connection identifier key, which includes connection

information for at least the remote client, the random input key being generated using

arbitrary information maintained secret by the local server;

ensuring that a same connection identifier does not have data collisions from

competing sequence numbers within a predetermined period of time, and ensuring

randomness of the initial sequence number on a per connection basis for preventing

attacks on the local server by monotonically incrementing a counter both a fixed value

based on a passage of a predetermined time period and a variable amount depending

upon a rate of connections with the local server, wherein if the rate of connections is

beyond a threshold value the variable increment is based on an elapsed time, otherwise

the variable increment is based on each connection established with the local server;

and

generating the initial sequence number by combining the intermediate value, the

fixed value and the variable amount.

12. The method of claim 11, wherein if the rate of connections is below the

threshold value, the fixed value is further incremented based on each connection

established with the local server.

13. The method of claim 12, wherein the fixed value is 25.6 K, and wherein

if a remote client's data transfer rate while connected to the local server is less than 256

K then the connection identifier used by the remote client the is allowed immediate re-

connection to the local server after the remote client disconnects.

14. The method of claim 11, wherein the connection identifier key further

includes connection information for one or more of the local server port, local server

routing address, remote port and remote routing address.

15. The method of claim 14, wherein the data transport protocol is

Transmission Control Protocol, and wherein the local and remote routing addresses are

Internet Protocol addresses.

- Page 33 -

16. The method of claim 11, wherein at least a second connection is made

between the local server and a second remote client, and wherein the method further

including the acts of:

receiving a second connection identifier key that includes connection

information for at least the second remote client;

securely initializing the hash function with at least a portion of the random input

key and at least a portion of the second connection identifier key for determining a

second intermediate value of a second initial sequence number;

based on at least a portion of the second connection identifier key, creating a

second monotonically increasing counter for ensuring that a same connection identifier

does not have data collisions from competing sequence numbers within a predetermined

period of time, and for ensuring randomness of the second initial sequence number on a

per connection basis for preventing attacks on the local server;

incrementing the second counter the fixed value based on the passage of the

predetermined time period;

incrementing the second counter a second variable amount depending upon a

rate of connections with the local server and for those connections associated with the

second counter, wherein if the rate of connections with the local server and for those

connections associated with the second counter is beyond a threshold value the variable

increment is based on an elapsed time, otherwise the variable increment is based on

each connection established with the local server and associated with the second

counter; and

combining the second intermediate value, the fixed value and the second

variable amount for generating the second initial sequence number.

17. The method of claim wherein 11, wherein the arbitrary information

maintained as a secret by the local server is based on timing, state conditions for the

local server, or both, at boot up time of the local server, which include one or more of a

time of day, a day of month, a month, a year, a local server hard drive head position,

and whether input was detected by hardware of the local server.

18. The method of claim 11, wherein the combining of the intermediate

value, the fixed value and the variable amount is a mathematical operation or function.

19. The method of claim 11, wherein if the rate of connections is beyond the

threshold value the variable increments up to an amount of 0x000022FB every

millisecond, otherwise the variable increment is an amount between 16 K and 32 K.

20. The method of claim 11, wherein the monotonically increasing counter is

shared by at least two connections at the same time.

21. For a local server that receives data from one or more remote clients over a data transport protocol, a computer program product comprising computer readable media carrying computer executable instructions that implement a method of generating an initial sequence number for use by a remote client when assigning sequence numbers to one or more data packets to be sent to the local server, the initial sequence number generated in a manner that prevents the local server from being attacked while

generating a random input key using arbitrary information maintained secret by the local server;

maintaining reliable data transfer, the method comprising the acts of:

receiving a connection identifier key that includes connection information for at least the remote client;

securely initializing a hash function with at least a portion of the random input key and at least a portion of the connection identifier key for determining an intermediate value of an initial sequence number;

creating a monotonically increasing counter for ensuring that a same connection identifier does not have data collisions from competing sequence numbers within a predetermined period of time, and for ensuring randomness of the initial sequence number on a per connection basis for preventing attacks on the local server;

incrementing the counter a fixed value based on a passage of a predetermined time period;

incrementing the counter a variable amount depending upon a rate of connections with the local server, wherein if the rate of connections is beyond a threshold value the variable increment is based on an elapsed time, otherwise the variable increment is based on each connection established with the local server; and

combining the intermediate value, the fixed value and the variable amount for

generating the initial sequence number.

22. The computer program product of claim 21, wherein if the rate of

connections is below the threshold value, the fixed value is further incremented based

on each connection established with the local server.

23. The computer program product of claim 22, wherein the fixed value is

25.6 K, and wherein if a remote client's data transfer rate while connected to the local

server is less than 256 K then the connection identifier used by the remote client the is

allowed immediate re-connection to the local server after the remote client disconnects.

24. The computer program product of claim 21, wherein the connection

identifier key further includes connection information for one or more of the local

server port, local server routing address, remote port and remote routing address.

25. The computer program product of claim 24, wherein the data transport

protocol is Transmission Control Protocol, and wherein the local and remote routing

addresses are Internet Protocol.

- Page 37 -

26. The computer program product of claim 21, wherein at least a second

connection is made between the local server and a second remote client, and wherein

the computer executable instructions further implement the method including the acts

of:

receiving a second connection identifier key that includes connection

information for at least the second remote client;

securely initializing the hash function with at least a portion of the random input

key and at least a portion of the second connection identifier key for determining a

second intermediate value of a second initial sequence number;

based on at least a portion of the second connection identifier key, creating a

second monotonically increasing counter for ensuring that a same connection identifier

does not have data collisions from competing sequence numbers within a predetermined

period of time, and for ensuring randomness of the second initial sequence number on a

per connection basis for preventing attacks on the local server;

incrementing the second counter the fixed value based on the passage of the

predetermined time period;

incrementing the second counter a second variable amount depending upon a

rate of connections with the local server and for those connections associated with the

second counter, wherein if the rate of connections with the local server and for those

connections associated with the second counter is beyond a threshold value the variable

increment is based on an elapsed time, otherwise the variable increment is based on

each connection established with the local server and associated with the second

counter; and

- Page 38 -

Docket No. 13768.491

combining the second intermediate value, the fixed value and the second

variable amount for generating the second initial sequence number.

27. The computer program product of claim wherein 21, wherein the

arbitrary information maintained as a secret by the local server is based on timing, state

conditions for the local server, or both, at boot up time of the local server, which

include one or more of a time of day, a day of month, a month, a year, the local server

hard drive position, and whether input was detected by hardware of the local server.

28. The computer program product of claim 21, wherein the combining of

the intermediate value, the fixed value and the variable amount is a mathematical

operand or function.

29. The computer program product of claim 21, wherein if the rate of

connections is beyond the threshold value the variable increments up to an amount of

0x000022FB every millisecond, otherwise the variable increment is an amount between

16 K and 32 K.

30. The computer program product of claim 21, wherein the monotonically

increasing counter is shared by at least two connections at the same time.

- Page 39 -

31. For a local server that receives data from one or more remote clients over

a data transport protocol, a computer program product comprising computer readable

media carrying computer executable instructions that implement a method of generating

an initial sequence number for use by a remote client when assigning sequence numbers

to one or more data packets to be sent to the local server, the initial sequence number

generated in a manner that prevents the local server from being attacked while

maintaining reliable data transfer, the method comprising the steps for:

determining an intermediate value of an initial sequence number by hashing a

random input key and a connection identifier key, which includes connection

information for at least the remote client, the random input key being generated using

arbitrary information maintained secret by the local server;

ensuring that a same connection identifier does not have data collisions from

competing sequence numbers within a predetermined period of time, and ensuring

randomness of the initial sequence number on a per connection basis for preventing

attacks on the local server by monotonically incrementing a counter both a fixed value

based on a passage of a predetermined time period and a variable amount depending

upon a rate of connections with the local server, wherein if the rate of connections is

beyond a threshold value the variable increment is based on an elapsed time, otherwise

the variable increment is based on each connection established with the local server;

and

generating the initial sequence number by combining the intermediate value, the

fixed value and the variable amount.

**WORKMAN NYDEGGER** 

32. The computer program product of claim 31, wherein if the rate of

connections is below the threshold value, the fixed value is further incremented based

on each connection established with the local server.

33. The computer program product of claim 32, wherein based on the fixed

value, if a remote client's data transfer rate while connected to the local server is less

than a specified byte rate then the connection identifier used by the remote client the is

allowed immediate re-connection to the local server after the remote client disconnects.

34. The computer program product of claim 31, wherein the connection

identifier key further includes connection information for one or more of the local

server port, local server routing address, remote port and remote routing address.

35. The computer program product of claim 34, wherein the data transport

protocol is Transmission Control Protocol, and wherein the local and remote routing

addresses are Internet Protocol.

36. The computer program product of claim 31, wherein at least a second

connection is made between the local server and a second remote client, and wherein

the computer executable instructions further implement the method including the acts

of:

receiving a second connection identifier key that includes connection

information for at least the second remote client;

securely initializing the hash function with at least a portion of the random input

key and at least a portion of the second connection identifier key for determining a

second intermediate value of a second initial sequence number;

based on at least a portion of the second connection identifier key, creating a

second monotonically increasing counter for ensuring that a same connection identifier

does not have data collisions from competing sequence numbers within a predetermined

period of time, and for ensuring randomness of the second initial sequence number on a

per connection basis for preventing attacks on the local server;

incrementing the second counter the fixed value based on the passage of the

predetermined time period;

incrementing the second counter a second variable amount depending upon a

rate of connections with the local server and for those connections associated with the

second counter, wherein if the rate of connections with the local server and for those

connections associated with the second counter is beyond a threshold value the variable

increment is based on an elapsed time, otherwise the variable increment is based on

each connection established with the local server and associated with the second

counter; and

- Page 42 -

Docket No. 13768.491

combining the second intermediate value, the fixed value and the second

variable amount for generating the second initial sequence number.

37. The computer program product of claim wherein 31, wherein the

arbitrary information maintained as a secret by the local server is based on timing, state

conditions for the local server, or both, at boot up time of the local server, which

include one or more of a time of day, a day of month, a month, a year, the local server

hard drive position, and whether input was detected by hardware of the local server.

38. The computer program product of claim 31, wherein the combining of

the intermediate value, the fixed value and the variable amount is a mathematical

operand or function.

39. The computer program product of claim 31, wherein if the rate of

connections is beyond the threshold value the variable increments up to an amount of

0x000022FB every millisecond, otherwise the variable increment is an amount between

16 K and 32 K.

40. The computer program product of claim 31, wherein the monotonically

increasing counter is shared by at least two connections at the same time.
